Carbonate reservoirs can be difficult to develop for a variety of reasons. They generally have poorer recoveries than siliciclastic sediments (e.g., Sun and Sloan). A combination of depositional geometry and diagenesis creates

Oolitic grainstones from a range of geologic ages and diagenetic histories are used to understand depositional sediment-pore relationships and how they evolve with lithification. Petrophysical variability within oolitic reservoirs may closely follow sedimentologic trends, which could be predictable.

Rock fabric controls on pore evolution and porosity ...

Carbonate cements formed in the early diagenesis stage can fill residual primary pores and reduce the reservoir quality.

However, the presence of carbonate cements can effectively reduce the compaction of rocks and provide a material basis for large-scale secondary corrosion in later
